

These settings are not protocol-comparable; the rows are not points on one axis and are never pooled into an overall rate.

reversal is defined at every recorded epoch, so no cell is missing from a row

■ reversed by epoch 1

■ reversed only by epoch 3

■ no reversal at any recorded epoch

Reversal = a sign change of centred NC3 for the same class, same convention, from that cell's own epoch-0 baseline. 'By epoch 1' counts cells whose sign had already changed at the first unlearning epoch; 'only by epoch 3' counts cells that first change sign at epoch 2 or 3.

Stratum F is excluded: its 5 cells are repeated observations of stratum C and E fc0 cells under different doses, and including them would double-count. No pooled rate across strata is computed or shown — the strata differ simultaneously in domain, input resolution, class count, dose protocol and test-set resolution.

The row ordering is not a dataset effect, not a class-count effect and not an effect of the objective; CIFAR-10 and the face lineages are not two points on one axis. The most controlled comparison in the project is the nested class-count sweep (strata A and B), which shows no reversals at any K — though it too moves a bundle of correlated quantities with K , not K alone.

No inferential claim is supported by the present analysis: these are counts of cells, and within a stratum the identities share a backbone per head, a split and a baseline checkpoint.
